# Hydrogen Chloride

1	)	Crop	DS			
1 2	Identification o	Identification of Petitioned Substance				
3 4	Chemical Names:	12	Trade Names:			
5	hydrogen chloride, HCl	13	none			
6		14				
7	Other Names:	15	CAS Numbers:			
8	anhydrous hydrochloric acid; chlorane;	16	7647-01-0			
9 10	chlorohydric acid; hydrogen chloride solution; muriatic acid.	17 18	Other Codes:			
10	munatic acid.	10	EC number: 231-595-7			
20		17				
21	Summary	of Pe	titioned Use			
22						
23			formation to the National Organic Standards Board			
24			loride, listed at 7 CFR 205.601(n), where it is allowed for			
25			ginally petitioned for use in 2002 (Wedel, 2002). It was			
26 27			added to the National List of Allowed and Prohibited , effective in 2006 (71 FR 53299). As part of the sunset			
27			2009, 2015, and in 2019 (NOSB, 2009a, 2015, 2019). In all			
28 29			y available solution for organic farmers needing to delint			
30			r 2019, a motion to remove hydrogen chloride from the			
31	National List was unanimously rejected by all 13 a					
32						
33			of relisting hydrogen chloride as essential and asserted			
34			e U.S. organic cotton industry. Allowing the limited use of			
35			economic and environmental benefits by supporting			
36			ng associated impacts of heavy pesticide use on			
37 38			ecialized research to support alternatives to hydrogen			
30 39	chonde, a causic and potentially harmin	1 mate	erial, were emphasized, and is supported by the NOSB.			
40	This technical report focuses on updates to the available	ailabil	ity of alternative substances and practices for cotton			
41	seed delinting.					
42	0					
43	Ва	ckgro	ound			
44		0				
45	At cotton (Gossynium hirsutum) maturity, the outer	rmost	layer of the cotton seed coat has two types of fibers:			
46			Linters are darker, shorter, more nearly cylindrical,			
47	and have thicker walls and narrower central canal					
48			w) but some fuzz (short fibers or linters) stays. The			
49			seed, thus creating conditions conducive for fungal			
50	infection (Afzal et al., 2020). In addition, the fuzz of					
51	planting (Delouche, 1986). <sup>1</sup> Delinting is a necessar	y pro	cess to improve storage and flowability of cotton			
52	seeds through equipment (Holt et al., 2017).					

53

54 The delinting process has only a very slight effect on the germination rate. Ryavalad et al. (2009) observed 55 that the germination rate of fuzzy seeds after nine months of storage was 66.3% as opposed to 68.3% for

56 acid delinted seed. McMichael et al. (2004) noticed that mechanical and acid delinting resulted in the same of

<sup>&</sup>lt;sup>1</sup> Grading is a process used by seed companies or storage facilities to classify seed based on physical characteristics such as size, shape, moisture content, color, texture, foreign matter, etc. This process ensures seed consistency.

57 germination rate and yield. Similarly, earlier research has shown that delinting does not necessarily affect

yields (Wilkes & Corley, 1968). An up-to-date account of cotton seed germination requirements is 58

59 adequately provided in Maeda et al. (2021). The importance of the delinting process is thoroughly

discussed by Atique-ur-Rehman et al. (2020). Historically, cotton seed has been delinted through chemical 60

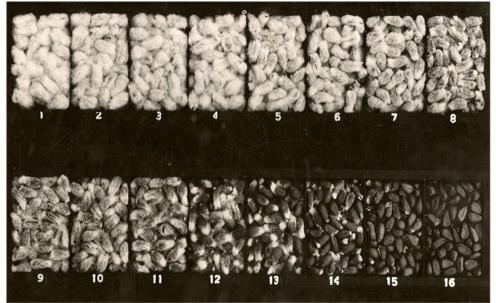

- or mechanical approaches (Delouche, 1986). 61
- 62 63

- 64 65

66 Figure 2: Variable degrees of cotton seed delinting. Fully delinted seed (16) is likely achieved using acid delinting (Anonymous author, source: https://file.scirp.org/Html/13-2600348\_20046.htm). 67

69						
70		ed process: hydrogen chloride				
71	The gas-acid or dry acid delinting method uses hydrogen chloride (anhydrous hydrochloric acid) to					
72	degrade the linters, which are then separated from the seed (Ardashev, 1933). This method is the most					
73		common method in Texas (Hopper & Hinton, 1979). It is most suitable when the cottonseed moisture				
74	content is <9%, as hydrogen chloride is a gas with a high affinity for water, and its penetration through the					
75		at into the embryo increases with higher seed moisture content (Delouche, 1986). In addition, high				
76		ity accelerates equipment corrosion, making the gas-acid method less adapted to humid regions				
77	(Delou	che, 1986).				
78						
79	The pro	ocess is as follows (Delouche, 1986):				
80 81	1)	Seeds with 5-7% moisture content are placed in a rotating drum at 60-70°C before injection of the gas-acid at a concentration of 0.5-2.0% of seed weight.				
82	2)	Seeds remain in the drum between 5 and 20 minutes, depending on the temperature, seed moisture				
83	,	content, concentration of the gas-acid and variety.				
84	3)	The degraded linters are removed by passing the seed through a perforated reel to allow the drop				
85	,	of the linters.				
86 87	4)	The acid is neutralized using ammonia, resulting in flowable seed ready for planting or storage.				
88	Gas-aci	d delinting uses less acid and is generally less expensive than another process, the wet acid method				
89		che, 1986). This method is discussed below, in <i>Evaluation Question</i> #11. However, the gas-acid				
90		l requires sophisticated equipment, close monitoring, and stringent control of the various operations				
91		ctive delinting without injury to the seed. Seed injury from the process can cause a drastic drop in				
92		ation and vigor. Seed injury can occur due to excessive temperature, gas-acid concentration,				
93	0	n duration, or too-long exposure to ammonia during neutralization. Poorly controlled gas-acid				
94		ng can cause a drastic reduction in germination and vigor (Delouche, 1986).

Provide a list of allowed inces that may be used in place of the petitioned substance (7 U.S.C. § 6518 (m) (6)). The extremely low pH (1.5-3) required for effective acid delinting, no non-synthetic substances are le as alternatives to synthetic acids for cotton seed delinting, However, alternative allowed practices ilable and detailed in the answer to <i>Evaluation Question</i> #12 (below). <i>ic Alternatives for Delinting</i> rom hydrogen chloride, no other synthetics on the National List are allowed for cotton delinting. to c acid (H <sub>2</sub> SO <sub>4</sub> ) is the most common material used for delinting (Afzal et al., 2020). However, sulfuric not currently an allowed material for delinting organic cotton. The NOP allows this material to be adjust the pH of liquid fish or liquid squid organic fertilizer products, provided that the amount bes not exceed the minimum needed to lower the pH to 3.5 (7 CFR 205.605(j)(8) & (10)). tion to sulfuric acid, other synthetic substances used in conventional cotton seed delinting include uch as anhydrous hydrochloric acid (gas) and alkanesulfonic acid (Borst & Zack, 2015). <i>owed process: wet-acid method (sulfuric acid)</i> ethod uses sulfuric acid, which is not allowed in organic production for cotton delinting. As detailed etha et al. (2021), cotton seed producers can use concentrated or diluted sulfuric acid.				

122 123 124	1)	Gin-run seeds are wetted with concentrated (93-98%) sulfuric acid at a dose of 80-140 mL/kg seeds with linters, with an acid/seed turning time of 7-8 min (Biradarpatil & Macha, 2009; Tostes et al., 2022).
125	2)	Seeds are washed with water for 2 min. After washing, seed is placed in water with a ratio of 1:10
126 127 128 129 130	3)	for removal of floaters. Seeds are immersed in a neutralizing solution for 10–15 min using one of the following basic compound: sodium hydroxide (NaOH), sodium carbonate (Na <sub>2</sub> CO <sub>3</sub> ), calcium hydroxide [Ca(OH) <sub>2</sub> ] (Tostes et al., 2022), calcium chloride (CaCl <sub>2</sub> ) (Atique-ur-Rehman et al., 2020) or different types of lime (Lima et al., 2023).
130 131 132	4)	Seeds are dried before moving to the cleaning, grading, treating, and packaging line.
132	In the	dilute wet-acid method:
133	1)	Dilute (~10%) sulfuric acid is used to wet the linters.
134	1) 2)	The wet seeds are then dewatered by centrifugation and dried with heated air to evaporate water,
135	(ک	increasing the concentration of the acid.
130	2)	
137	3)	The degraded (hydrolyzed) linters are removed by frictional forces in a rotating buffer-drum.
138	4)	Residual acidity is neutralized with ammonia or by adding lime in the seed treatment process
139		(Delouche, 1986).
140	Thoad	vantages of the dilute wet-acid delinting process are:
141	The au	Reduction in the quantity of sulfuric acid required (due to lower quantity used and recovery
142	•	during dewatering).
144	•	Elimination of the effluent produced in wet-acid delinting.
145	•	Production of by-products (hydrolyzed linters removed during the buffer-drum step) that have
146		potential value in ethanol production and as an animal feed additive (Delouche, 1986).
147 148	Non al	lowed process: alkanesulfonic acid
140		esulfonic acid is another synthetic material that has been recently reported for cotton delinting. Like
149		
150		c acid, this method is not allowed in organic production. BASF applied for a patent for this material (Borst & Zack, 2015). This method comprises:
151	1)	Applying alkanesulfonic acid to surfaces of linted cotton seeds, and optionally heating the linted
152	1)	cotton seeds. A surfactant and water are added to the acid.
155	2)	Applying mechanical force to the surfaces of the linted cotton seeds.
154	(ک	Apprying mechanical force to the surfaces of the infled cotton seeds.
155	No ovr	perimental evidence of the use or efficacy of this material is available in scientific literature.
150	-	elinting, however, can easily cause damage to seed viability with improper acid exposure time. It
157		o been reported to reduce seed shelf life and is a relatively expensive process.
150	1105 015	been reported to reduce seed shell life and is a relatively expensive process.
160	Evalua	tion Question #12: Describe any alternative practices that would make the use of the petitioned
161		nce unnecessary (7 U.S.C. § 6518 (m) (6)).
162		cally, three different methods have been used to delint cotton seeds: mechanical, flaming and
163		al (Delouche, 1986). Mechanical and flaming methods were more common before the development
164		delinting methods (Bourland, 2019). Earlier researchers found that although fuzzy seeds tended to
165		e more slowly, little difference in stands or yields existed between fuzzy, acid-delinted, and
166	•	nically delinted seed (Wilkes & Corley, 1968).
167		y , , , , , , , , , , , , , , , , , , ,
168	Mechar	iical delinting
169		nical delinting is another method to minimize the amount of lint on the seed. In the mechanical
170		s, physical abrasion removes the fuzz from the surface of seed (Holt et al., 2017). This method
171		es effort and time but it preserves the seed from chemical injuries (Armijo et al., 2006).
172	1	
173	Mecha	nical delinting can reduce the lint amount down to 1.5% (weight/weight) (Olivier et al., 2006). The
174		l weight/weight of lint is not provided. The duration of mechanical delinting can affect cottonseed
175		. Hopper et al. (2003) reported that mechanical delinting for 10 minutes was generally equal to or

176 superior to 20- and 60-minute delinting times. The USDA cotton research group in Texas has successfully

- built a commercial scale mechanical delinter. However, up to the date of writing this report, there has beenno industrial partner ready to manufacture it (Greg Holt, personal communication). Seed handling and
- 176 no incustrial partier ready to manufacture it (Greg Floit, personal communication). Seed handling and planting flowability of mechanically delinted seed can be further improved by seed coating, which can be
- done using natural or synthetic compounds. This is a practice that has been used in preparing cottonseed
- 181 as animal feed. Natural compounds used include plant starches (maltodextrins) and gum Arabic (Afzal et
- al., 2020). Corn starch has been successfully used for cotton seed (Hopper et al., 2003).
- 183
- 184 In one study, researchers evaluated two cotton cultivars: one that involved mechanically-treated seed
- coated with gelatinized corn starch (called EasiFlo), versus another that was delinted with an undisclosed
- 186 acid (Olivier et al., 2006). The mechanical delinting process reduced the residual linters on the seed to about
- 187 1.5% by weight. Three seed-vigor tests (warm germination test, cool germination test, and cool warm vigor
- index) resulted in similar results for both seed treatments. Moreover, three commercial-scale field
  experiments showed that lint yield was not statistically different between the two treatments (Olivier et al.,
- 190 2006).
- 191
- 192 *Flame delinting*
- 193 Flame delinting or zipper delinting is a process used by seed processing facilities on mechanically delinted
- seed which are dropped through an intense flame to singe or burn off loose linters. Flowability of the
- 195 cotton seed is substantially improved, but not sufficiently for precision cleaning and conditioning methods
- 196 which separate despined cockleburs and immature, low density seeds (Delouche, 1986). The seeds exposed
- 197 to flaming need to be cooled down quickly to avoid damage to the embryo that might affect germinability
- 198 and vigor (Delouche, 1986).
- 199

### 200 *Chemical (acid) delinting*

- Acid delinting was developed in response to the drawbacks of mechanical delinting. Mechanical processes
- damaged the seed physically or by the heat generated from repeated friction with the seed, therefore
- weakening or killing the embryo (Delouche, 1986). In addition, mechanical delinting alone was not very
- efficient at removing the linters off the seed (Delouche, 1986). Acid delinting also has the added benefit of
- reducing microbial contamination and seed-borne pathogens (Chohan et al., 2020; Delouche, 1986). As a
- result, most cotton planting seed in the U.S. are acid delinted using either hydrochloric acid (dry acid
- 207 method) or dilute sulfuric acid (wet acid method) (Pilon et al., 2016).
- 208
- 209 Breeding fuzzless seed
- 210 A fuzzless upland cotton mutant (9023  $n_4^t$ ) was developed from the cultivar 'SC 9023' through chemical
- 211 mutagenesis by the Texas USDA cotton research group and Texas Tech University in Lubbock (Bechere et
- al., 2012). This mutant strain gins faster and with less energy when compared to other conventional and
- transgenic cultivars (Bechere et al., 2011). Early breeding efforts have continued to show that another
- 214 fuzzless genotype is possible through identification of genes controlling fuzz fiber production (Erpelding,
- 215 2016b). Until 2016, four fuzzless genotypes have been identified in the USDA *Gossypium arboretum*
- collection, which would suggest the presence of multiple genes for the fuzzless trait in this germplasm
- collection (Erpelding, 2016a). These genotypes could be potential breeding candidates to develop fuzzless
- cotton cultivars that would remove or reduce the need for cottonseed delinting.
- 219 220

221

230

# Focus Questions Requested by the NOSB

- Focus Question #1. What new alternative substances or practices, if any, have become available since
  the last limited scope report in 2014? Are there any updates regarding the mechanical cottonseed
  delinter made by the USDA and referenced in the 2014 report on hydrogen chloride?
- 225 Researchers at the USDA-ARS Cotton Production and Processing Research Unit in Lubbock, Texas,
- describe construction of a prototype small-scale benchtop mechanical cotton seed delinter (Holt et al.,
- 227 2017). The researchers evaluated different drum linings and different roller brush combinations for
- 228 "scrubbing" lint from the cotton seed. In addition, two processing times (five and ten minutes) were
- 229 evaluated. Researchers measured the following parameters:
  - lint loss (i.e., residual lint remaining on the seed after processing)

- germination
  - visible mechanical damage of the seed
- visual observations of durability
- 234

232

The researchers found that an alternating brush pattern of half nylon and half steel wire bristle brushes is the best drum material using either one or two roller brushes (Holt et al., 2017). The best processing time in terms of the lint loss values was ten minutes. Lint loss values of the seed with one or two roller brushes at ten minutes were 0.95% and 0.88%, respectively. Germination rates for seed delinted using this system at five and ten min were not statistically different (89.3% and 88.4%, respectively). The brush material used (42N42W) appeared to be the most durable and was one of the easiest materials evaluated to clean out between samples (Holt et al., 2017).

242

Based on the bench-top prototype detailed in (Holt et al., 2017), the group built an 8-ft commercial scale

- prototype that could delint approximately 1000 lb./hour of fuzzy upland cottonseed (Figure 3, Figure 4)
  (Greg Holt, personal communication). The delinter will be tested at a commercial cotton gin in New
- 246 Mexico during the 2023-2024 ginning season. To complement the mechanical delinter, a cottonseed
- 246 Mexico during the 2023-2024 girling season. To complement the mechanical definiter, a cononseed 247 preconditioning system was also developed to handle several tons of seed per hour. The preconditioning
- system is designed to remove 4 to 6% of residual lint from fuzzy upland cotton prior to the mechanical
- 248 system is designed to remove 4 to 6% of residual lint from fuzzy upland cotton prior to the mechanical 240 delinter to impress the processing throughout (Creat Holt, personal communication). Preliminary test
- delinter to improve the processing throughput (Greg Holt, personal communication). Preliminary tests
- have shown that lint percentage dropped from 12.4% in initial fuzzy seed to 8.4% with two passes in the
- delinter (Holt et al., 2022). A larger version of the 8-ft mechanical delinter could be developed if a
  manufacturing company decides to adopt it. However, as of the development of this report, no such
- manufacturing company decides to adopt it. However, as of the development of this report, no sucharrangements are planned (Greg Holt, personal communication).
- 255 254
- 255 Other techniques to improve cotton seed germination
- 256 Seed plasma treatment is a new, non-chemical approach to sanitize seeds and protect against fungi and
- bacteria (de Groot et al., 2018). Plasma is formed by an electric discharge in a gas. In the case of an air
- 258 plasma it consists of ions, energetic electrons, neutral species, reactive oxygen species and reactive nitrogen
- 259 species, and produces electromagnetic radiation such as UV. Cold plasma treatment of cotton seeds
- significantly improved water absorption and germination parameters, including the four-day warm-
- 261 germination and metabolic-chilling tests, and seed imbibition. This method could be promising in
- 262 providing protection during storage to conserve or improve germination of seed delinted mechanically or
- using other organically-approved methods (de Groot et al., 2018).
